ABSTRACT

Objective. To assess the relationship between antihypertensive drugs, loop diuretics and the risk of hospitalization for hip fracture (HF).

Design. A population-based study was carried out in a cohort of 81,617 patients from Lombardy (Italy) aged 70-90 years who were newly treated with antihypertensive agents or loop diuretics between 2005 and 2009. Cases were the 2,153 patients who experienced the outcome (hospitalization for HF within December 31, 2012). For each case, up to three controls were randomly selected from the cohort to be matched for gender, age at cohort entry, and date of initial prescription. The case-control and case-crossover designs and the logistic regression for matched sets were used to measure the strength of the association between current use of an antihypertensive drug (within 30 days before the HF hospitalization) and the risk of outcome.

Results. Case-control and case-crossover odds ratios for current use of loop diuretics were 1.67 (95% CI: 1.28 to 2.18) and 1.49 (1.05 to 2.10) respectively. Among patients aged 81-90 years, case-control and case-crossover odds ratios were 1.52 (1.04 to 2.21) and 1.82 (1.10 to 3.00) for current use of loop diuretics, 1.86 (1.03 to 3.35) and 1.88 (1.01 to 3.48) for α -blockers. No other agent was associated with the outcome.

Conclusions. Evidence that loop diuretics and α -blockers are associated with higher risk of HF was consistently supplied by two observational approaches. Clinicians should carefully consider the risk of falls in their selection of drugs for hypertension and in the clinical use of loop diuretics.

Keywords. Antihypertensive drugs; Loop diuretics; Case-crossover design; Elderly; Healthcare Databases; Hip fracture; Nested case-control study; Risk of falls

KEY POINTS

- Newly prescribed antihypertensive medications, when considered together as a whole class, do not determine a greater risk of hip fracture in the older patients. However, especially in the oldest, α -blockers and loop diuretics may increase this risk.
- Rapid reduction of circulating fluid volume and/or systematic vasodilatation, should be avoided in the elderly because they are mechanisms highly likely to cause a fall and consequent hip fracture.

1. INTRODUCTION

Randomized clinical trials have repeatedly shown that antihypertensive drug treatment reduces the risk of hypertension-related morbid and fatal events in older patients [1], including subjects aged 80 years and older, who show a favorable benefit-harm ratio for antihypertensive treatments [2,3]. However, elderly hypertensive patients recruited for randomized clinical trials have almost invariably been characterized by better health status than those in real life practice. This difference is particularly marked in the so far sole trial addressing octogenarian hypertensives [4-6]. Furthermore, in randomized clinical trials physicians' expertise and patients' close follow-up favor optimal treatment delivery, minimizing its side effects [7], but the real-life tolerability profile of elderly patients may differ [8].

Falls are a well-known geriatric syndrome, which often lead to serious injuries such as fractures. Among them, hip fracture (HF) is considered a key proxy of falls [9]. Major risk factors for falls are balance and gait impairment, dizziness, and postural hypotension, which are among the most common adverse effects of antihypertensive medications [10-12]. A meta-analysis of observational studies showed a 24% increased odds of falling associated with the use of antihypertensive agents [13], even though the studies varied in the extent of adjustment for confounding factors. As a result, it is unclear

1 whether (and to what extent) these findings are attributable to differences between individuals – i.e.
2 comorbidity and other confounders – or to the effect of antihypertensive agents per se [14].

3
4 Data are conflicting concerning the effect of different antihypertensive medications on the occurrence
5 of falls and fractures [13-19]. There is inconsistency in reports of a reduction in fracture risk with β -
6
7 blockers [20-24], calcium channel blockers [15], ACE inhibitors [16,17] and angiotensin receptor
8
9 antagonists [25]. Loop diuretics as a class have been associated with an increased risk of HF in some
10
11 [17,26,27], but not all [28,29] studies.

12
13 We performed a large population-based investigation nested into a cohort of individuals aged between
14
15 70 and 90 years newly treated with antihypertensive drugs or loop diuretics, to assess whether current
16
17 exposure to these agents increases the risk of HF.

2. METHODS

2.1 Setting

18 Lombardy is a Northern Italian region that accounts for about 16% (almost ten million) of the total
19
20 population. In Italy, all the citizens are covered by the National Health Service (NHS), and in
21
22 Lombardy this has been associated since 1997 with an automated system of databases to collect a
23
24 variety of information. We retrieved data from the Lombardy healthcare utilization databases, whose
25
26 details and uses in the fields of hypertension are reported elsewhere [30-34].

2.2 Cohort and follow-up

27 We included all residents aged 70 to 90 years. Of these, we identified those who received at least one
28
29 antihypertensive medication or loop diuretic anytime between 2005 and 2009, defining the first
30
31 dispensation as the initial prescription. The medications included blockers of the renin-angiotensin
32
33 system (i.e. ACE-inhibitors and ARBs), α -blockers, β -blockers, calcium channel blockers (CCBs),

1 loop- and non-loop diuretics. The complete list of drugs is in the Supplementary Table 1. Although
2 these drugs may be used for treating conditions other than hypertension, and loop diuretics are not
3 indicated as primary antihypertensives, we will refer to them henceforth collectively as blood-
4 pressure lowering medications.
5

6
7 On the basis of the 5-year interval before the initial prescription, patients were excluded if they had
8 already received any blood-pressure lowering medication (to ensure inclusion of newly treated
9 individuals), or displayed characteristics suggestive of high risk of falls and/or bone fracture, such as
10 hospital admissions for selected causes or prescriptions of selected medications. The former,
11 identified by the ICD-9 code for hospital admissions, included: malignant neoplasm, traumatic injury,
12 Paget's disease, osteomalacia, Cushing syndrome, coeliac disease, hyperthyroidism, hyper-
13 parathyroidism, Parkinson's disease, orthostatic hypotension, blindness, balance disorders, dementia,
14 cerebrovascular disease and chronic liver disease. The selected medications, identified by the ATC-
15 codes of outpatient drug prescriptions, consisted of bisphosphonates, calcitonin, raloxifene,
16 corticosteroids, antineoplastic agents, and medications used for thyroid therapy. With the aim of
17 ensuring enough observation for applying exclusion criteria, patients who did not result registered
18 into the NHS from at least five years before the initial prescription were excluded.

19 The patients included into the final cohort accumulated person-years of follow-up from the initial
20 prescription until the earliest date among hospital admission for HF (outcome), death, emigration, or
21 December 31st, 2012.

22 **2.3 Cases and controls**

23 Cases were those who experienced the outcome "hospitalization for HF" during the follow-up,
24 identified by the related ICD-9 code (820.x). The earliest date of hospital admission recorded with
25 this code was considered as the event date. Three controls for each case were selected randomly
26 within the cohort after they were matched on gender, age at cohort entry (± 3 years), date of cohort
27 entry, and did not yet have experienced the outcome at the time of the matched case event (index
28 date).

2.4 Exposure

For each case and control all blood-pressure lowering medications dispensed from initial prescription until the index date were identified. Prescriptions during the 30-day period before the index date were considered to identify current exposure to any blood-pressure lowering medication. The last prescription before the outcome onset within the current time was considered for classifying patients according to 1) exposure to specific blood-pressure lowering classes, i.e., ACE-inhibitors and ARBs together, α -blockers, β -blockers, CCBs, loop diuretics, and non-loop diuretics; 2) antihypertensive treatment strategy, i.e. if one (monotherapy), or two or more agents (combined therapy) were dispensed. Combined therapy was regarded as either, a fixed-dose combination or an extemporaneous combination of two or more drugs dispensed at the same date.

2.5 Covariates

We included prescriptions of drugs used for selected diseases known to be associated with increased risk of fall (i.e., antidepressants, neuroleptics and hypoglycaemic agents [35,36]). Additionally, we recorded the use of statins, which has been consistently associated with decreased risk of HF [37]. The prescriptions of these medications were recorded for the 5-year period before the initial prescription. Information about the use of other drugs suspected to affect the postural control (i.e., digoxin, benzodiazepines, antiarrhythmics, and antiepileptics [38]) in the 30-day period before the hip fracture was also included. Finally, the diagnosis available from the inpatient charts over five years before the initial prescription date was used to calculate the Charlson comorbidity index [39].

2.6 Data analysis

Two approaches of data analysis were used (**Figure 1**). One, the case-control approach was used by contrasting the current exposure of each case with that of the three matched controls. A conditional logistic regression for 1:3 matched case-control data was used to estimate the odds ratio (OR), and 95% confidence interval (CI), of HF associated with the current exposure to blood-pressure lowering medications. Estimates were adjusted for the above reported covariates including drug prescriptions during the 5-year period (i.e., antidepressants, neuroleptics, hypoglycaemic agents, and statins) and

1 the 30-day period (i.e., digoxin, benzodiazepines, antiarrhythmics, and antiepileptics) before the
2 index date, as well as the Charlson comorbidity index (categorized according to scores 0, 1 or ≥ 2).
3
4
5 3 Two, the case-crossover approach was used to estimate the effect of current exposure on the
6
7 4 considered outcome [40]. To this end, the current exposure of each case was contrasted with three
8
9
10 5 previous reference periods (each of 30-day width) within each case patient. A wash-out period
11
12 6 between the current and the most recent reference period was allowed to avoid a carryover effect. By
13
14
15 7 comparing cases to themselves at different points in time, the case-crossover approach automatically
16
17 8 controls for confounding by attributes that are constant over time. A conditional logistic regression
18
19 9 model for 1:3 matched data was again used to estimate the OR for current exposure to blood-pressure
20
21
22 10 lowering medications. Estimates were adjusted for the use of digoxin, benzodiazepines,
23
24 11 antiarrhythmics, and antiepileptics during the current and referent periods.
25
26
27 12 It should be considered that, according with the case-crossover design, exposure to blood-pressure
28
29 13 lowering medications and other agents must to be assessed during a time-window large enough to
30
31
32 14 include current and referent periods, as well as the wash-out period. We therefore need a long enough
33
34 15 time-window before the index date for assessing exposure of all case patients. For this reason, cases
35
36 16 who did not reach at least 6 months of follow-up were excluded. Furthermore, although a shorter
37
38
39 17 time-window was requested for the case-control design, we preferred to use the same exclusion
40
41 18 criterion for ensuring results comparability.
42
43
44 19 Data were separately analysed for two age subgroups (70-80 and 81-90 years). Shorter (15 days) and
45
46 20 longer (45 and 90 days) definitions of exposure were also considered to verify the robustness of case-
47
48
49 21 control and case-crossover findings.
50
51 22 All analyses were performed using the Statistical Analysis System software version 9.4 (SAS
52
53 23 Institute, Cary, NC, USA). Statistical significance was set at the 0.05 level. All p-values were two-
54
55
56 24 sided.

3. RESULTS

3.1 Patients

The selection of the final cohort is detailed in **Figure 2**. The 81,617 patients accumulated 406,953 person-years of observation (on average 5.0 years per patient), and generated 2,331 first hospital admissions for HF. Of these, the 178 patients who experienced the outcome within the first six months of follow-up were excluded. The remaining 2,153 HF hospitalizations were included as cases and were matched to 6,450 controls. At the date of the initial prescription mean age (\pm SD) of cases and controls was 79 years (\pm 5 years), and 24% of them were men.

Some selected characteristics of the study population, as well as of risk and referent periods within cases, are summarized in **Table 1**. HF was preceded by a 30-day blood-pressure lowering medication treatment in about one third of the cases with no significant difference from controls. There was no evidence that cases and controls differ for the currently employed treatment strategy. A higher proportion of cases than controls was currently exposed to α -blockers ($p=0.036$), loop diuretics ($p<0.001$), benzodiazepines ($p<0.001$), and antiepileptic agents ($p<0.001$). The proportion of patients under statin treatment was lower in cases than in controls ($p=0.008$), whereas the reverse was observed for antidepressants and neuroleptics (both $p<0.001$). Charlson comorbidity index was similar in cases and controls. Cases were more frequently exposed to loop diuretics ($p=0.021$) during the current period than during the referent one.

3.2 Case-control estimates

There was statistical evidence that current exposure to α -blockers and loop diuretics increased the HF risk of 69% (95% CI 4% to 176%) and 67% (95% CI 28% to 118%) respectively (**Figure 3**). Current exposure to loop diuretics resulted significantly associated with the HF risk among both younger and older patients, whereas evidence that α -blockers exert their action on the considered outcome resulted only for older patients. (**Table 2**). There was no evidence that current exposure to blood-pressure lowering medications as a whole (including or excluding loop diuretics), as well as blood-pressure lowering medication dispensed as monotherapy or combined therapy affected the HF risk (**Figure 4**).

3.3 Case-crossover estimates

Figure 3 shows that current exposure to loop diuretics significantly increased the HF risk of 49% (95% CI 5% to 110%). The risk associated with current use of α -blockers observed from case-control estimates was not confirmed from the case-crossover estimate. However, older patients currently using α -blockers and loop diuretics had increased HF risks of 88% (95% CI 1% to 248%) and 82% (95% CI 10% to 200%) respectively (**Table 2**). Again, there was no evidence that current exposure to blood-pressure lowering medications as a whole (including or excluding loop diuretics), as well as treatment strategy affected the HF risk (**Figure 4**).

Sensitivity analysis

Results did not substantially change by shortening at 15 days or lengthening at 45 and 90 days the definition of current exposure (results shown in **Supplementary Table 2**).

4. DISCUSSION

This study shows that elderly subjects newly treated with blood-pressure lowering medications as a whole in a real life setting did not exhibit a greater risk of HF. Nevertheless, considering the single classes, current use of loop diuretics resulted consistently associated with an increased HF risk among the entire cohort of patients aged 70 to 90 years (1.5-fold increased risk), as well as among those aged 81-90 years (1.8-fold increased risk). The category of older patients currently exposed to α -blockers had also a 1.9-fold increased HF risk.

The mechanism for loop diuretics involves rapid reduction in circulating plasma volume and for α -blockers vasodilatation due to α -adrenergic blockade [41]. Because advanced age is associated with diminished organ and homeostatic reserve, the susceptibility of older people to the adverse effects of these mechanisms is correspondingly greater.

Several features of this study should be mentioned to interpret these findings. First of all, the increased risk was observed using two different approaches, namely case-control and case-crossover designs.

1 Case-control is vulnerable to confounding, including confounding due to physical and cognitive
1
2 2 conditions typical of advanced age which often remain unmeasured. The case-crossover design is not
3
4 3 vulnerable to confounding by factors that remain constant within individuals, but is vulnerable to
5
6
7 4 confounding arising from time-trends in exposure or confounders. Although these designs use entirely
8
9
10 5 different sets of controls, very similar results were obtained in the current application. This doubtless
11
12 6 strengthens the validity of our findings.

13
14 7 Because we designed the study to investigate the acute effect of taking blood-pressure lowering
15
16
17 8 medications in the period before the HF outcome, the findings do not indicate a longer term lowering
18
19 9 effect of loop diuretics or antihypertensive agents on bone mineral density [18,23]. Rather, they likely
20
21
22 10 reflect the hypotensive effect of impairing sympathetic vascular influences or reducing blood volume
23
24 11 [42,43] with associated symptoms such as dizziness, fainting, or syncope [44,45]. Indeed, impaired
25
26
27 12 blood pressure homeostasis [46] and urinary symptoms during night-time [17] could facilitate
28
29 13 injurious falls.

30
31 14 We also remark that a case-crossover design needs of a sufficient time frame for retrospectively
32
33
34 15 investigating the exposure of interest. Evidence suggests that initiation of blood-pressure lowering
35
36
37 16 medication in the immediate post-exposure period is largely associated with orthostatic hypotension
38
39 17 [42,45,47]. This likely explain why, in contrast with other studies involving elderly patients [16], we
40
41 18 did not find that antihypertensive drug treatment as a whole increased the risk of HF. Rather, the case-
42
43
44 19 crossover design sheds light on the differential effect of switching between drug classes. Similar
45
46
47 20 findings were reported by a recent case-crossover study, which showed a two-fold increased risk of
48
49 21 HF shortly after starting loop diuretic treatment [17]. On the other hand, we did not confirm results
50
51
52 22 from case-only studies reporting significant associations between transitory use of β -blockers [14],
53
54 23 ACE inhibitors [16], ARBs [25] and CCBs [48] with the risk of falls. At our best knowledge, there
55
56 24 are no other studies that demonstrated an increased risk of HF with use of α -blockers.

1 Furthermore, we enlightened that the risk of HF is significantly increased among users of
2 benzodiazepines, antiepileptics, antidepressants and neuroleptics, confirming the increased risk of
3 falls during treatment with psychotropic drugs [38].

4
5 Finally, the size of the observed association, jointly with the prevalence of loop diuretic prescriptions
6 in our patient sample (slightly less than 3%), suggests that less than 3% of HFs in elderly
7 hypertensives are attributable to acute use of loop diuretics. Etiological fraction is expected to be
8 about 5% for α -blockers. This means that, in our setting, almost one out of twelve hospital admissions
9 for HF are probably due to current exposure to antihypertensive drugs. This represents a warning that
10 should always remind physicians of the possibility of accidental falls and their related consequences
11 when antihypertensive treatment is prescribed in the elderly.

12 This study has some limitations. One, we were unable to determine whether participants adhered with
13 drug prescriptions. However, reliable measures of adherence can hardly be employed in large-scale
14 population studies. Furthermore, poor adherence would have made the adverse effects even greater
15 with respect to α -blockers and loop diuretics. Two, it is impossible to determine whether the observed
16 HFs were related to falls. However, a study on post-menopausal women showed that more than 95%
17 of HFs are linked to a fall [9], which suggests that this was indeed the main risk factor for the
18 considered outcome. Three, because our HCU databases did not report diagnostic information,
19 patients may have had conditions other than hypertension. This clearly applies in the case of loop
20 diuretic use, for which the commonest indication is congestive heart failure. However, if we consider
21 the clinical indications of the use of antihypertensive drugs in Italy, hypertension per se represents by
22 far the most common diagnosis (73%), and only about 20% are prescribed for angina pectoris,
23 myocardial infarction and heart failure, and less than 1% for non-chronic indications, such as oedemas
24 [49]. Four, case-crossover estimates are open to bias from confounders that vary with time including,
25 in the present study, seasonality of HF risk [50]. However, although a certain seasonality in the risk
26 of fractures has been reported [51], to the best of our knowledge there is no evidence that this aspect
27 might substantially affect antihypertensive therapy. Rather, we cannot exclude that worsening clinical

1 profile (likely leading to change therapeutic strategy and increase the risk of fall) may partly explain
2 the observed risk excesses.

5. CONCLUSION

3
4
5
6
7
8
9
10
11
12 This large population-based study in a setting of real practice confirms previous evidence of an
13
14 increased risk of HF among elderly who newly use loop diuretics. Some evidence that α -blockers
15
16 might play a causal role in the onset of HF has been also supplied. Given the potential for bias and
17
18 the conflicting results from the existing literature on this issue, additional high quality studies are
19
20 needed. Meanwhile, with the aim of reducing the burden of HF, which ranges from the individual
21
22 disability to the social costs, it is important to direct every effort to counteract the worldwide
23
24 increasing trend. In this scenario, the careful consideration of the most appropriate antihypertensive
25
26 drug strategy plays a fundamental role.
27

SOURCES OF FUNDINGS

Supports for this study come from the Italian Minister of the Education, University and Research grants (“Fondo d’Ateneo per la Ricerca” portion, year 2014).

DISCLOSURES

G.C. received research support from the European Community (EC), the Italian Agency of Drug (AIFA), and the Italian Minister for University and Research (MIUR). He took part to a variety of projects that were funded by pharmaceutical companies (i.e., Novartis and GSK). He also received honoraria as member of Advisory Board from Roche.

G.M. has received honoraria for participation as speaker/chairman in national/international meetings from Bayer, Boehringer Ingelheim, CVRx, Daiichi Sankyo, Ferrer, Medtronic, Menarini Int., Merck, Novartis, Recordati and Servier.

P.M., M.M.C., F.R., L.M., G.A. declare that they have no conflict of interest.

COMPLIANCE WITH ETHICAL STANDARDS

Research involving human participants and/or animals: The present research did not involve any trial on human participants or animals.

ABSTRACT

Objective. To assess the relationship between antihypertensive drugs, loop diuretics and the risk of hospitalization for hip fracture (HF).

Design. A population-based study was carried out in a cohort of 81,617 patients from Lombardy (Italy) aged 70-90 years who were newly treated with antihypertensive agents or loop diuretics between 2005 and 2009. Cases were the 2,153 patients who experienced the outcome (hospitalization for HF within December 31, 2012). For each case, up to three controls were randomly selected from the cohort to be matched for gender, age at cohort entry, and date of initial prescription. The case-control and case-crossover designs and the logistic regression for matched sets were used to measure the strength of the association between current use of an antihypertensive drug (within 30 days before the HF hospitalization) and the risk of outcome.

Results. Case-control and case-crossover odds ratios for current use of loop diuretics were 1.67 (95% CI: 1.28 to 2.18) and 1.49 (1.05 to 2.10) respectively. Among patients aged 81-90 years, case-control and case-crossover odds ratios were 1.52 (1.04 to 2.21) and 1.82 (1.10 to 3.00) for current use of loop diuretics, 1.86 (1.03 to 3.35) and 1.88 (1.01 to 3.48) for α -blockers. No other agent was associated with the outcome.

Conclusions. Evidence that loop diuretics and α -blockers are associated with higher risk of HF was consistently supplied by two observational approaches. Clinicians should carefully consider the risk of falls in their selection of drugs for hypertension and in the clinical use of loop diuretics.

Keywords. Antihypertensive drugs; Loop diuretics; Case-crossover design; Elderly; Healthcare Databases; Hip fracture; Nested case-control study; Risk of falls

KEY POINTS

- Newly prescribed antihypertensive medications, when considered together as a whole class, do not determine a greater risk of hip fracture in the older patients. However, especially in the oldest, α -blockers and loop diuretics may increase this risk.
- Rapid reduction of circulating fluid volume and/or systematic vasodilatation, should be avoided in the elderly because they are mechanisms highly likely to cause a fall and consequent hip fracture.

1. INTRODUCTION

Randomized clinical trials have repeatedly shown that antihypertensive drug treatment reduces the risk of hypertension-related morbid and fatal events in older patients [1], including subjects aged 80 years and older, who show a favorable benefit-harm ratio for antihypertensive treatments [2,3]. However, elderly hypertensive patients recruited for randomized clinical trials have almost invariably been characterized by better health status than those in real life practice. This difference is particularly marked in the so far sole trial addressing octogenarian hypertensives [4-6]. Furthermore, in randomized clinical trials physicians' expertise and patients' close follow-up favor optimal treatment delivery, minimizing its side effects [7], but the real-life tolerability profile of elderly patients may differ [8].

Falls are a well-known geriatric syndrome, which often lead to serious injuries such as fractures. Among them, hip fracture (HF) is considered a key proxy of falls [9]. Major risk factors for falls are balance and gait impairment, dizziness, and postural hypotension, which are among the most common adverse effects of antihypertensive medications [10-12]. A meta-analysis of observational studies showed a 24% increased odds of falling associated with the use of antihypertensive agents [13], even though the studies varied in the extent of adjustment for confounding factors. As a result, it is unclear

1 whether (and to what extent) these findings are attributable to differences between individuals – i.e.
2 comorbidity and other confounders – or to the effect of antihypertensive agents per se [14].

3 Data are conflicting concerning the effect of different antihypertensive medications on the occurrence
4 of falls and fractures [13-19]. There is inconsistency in reports of a reduction in fracture risk with β -
5 blockers [20-24], calcium channel blockers [15], ACE inhibitors [16,17] and angiotensin receptor
6 antagonists [25]. Loop diuretics as a class have been associated with an increased risk of HF in some
7 [17,26,27], but not all [28,29] studies.

8 We performed a large population-based investigation nested into a cohort of individuals aged between
9 70 and 90 years newly treated with antihypertensive drugs or loop diuretics, to assess whether current
10 exposure to these agents increases the risk of HF.

2. METHODS

2.1 Setting

11 Lombardy is a Northern Italian region that accounts for about 16% (almost ten million) of the total
12 population. In Italy, all the citizens are covered by the National Health Service (NHS), and in
13 Lombardy this has been associated since 1997 with an automated system of databases to collect a
14 variety of information. We retrieved data from the Lombardy healthcare utilization databases, whose
15 details and uses in the fields of hypertension are reported elsewhere [30-34].

2.2 Cohort and follow-up

16 We included all residents aged 70 to 90 years. Of these, we identified those who received at least one
17 antihypertensive medication or loop diuretic anytime between 2005 and 2009, defining the first
18 dispensation as the initial prescription. The medications included blockers of the renin-angiotensin
19 system (i.e. ACE-inhibitors and ARBs), α -blockers, β -blockers, calcium channel blockers (CCBs),

1 loop- and non-loop diuretics. The complete list of drugs is in the Supplementary Table 1. Although
2 these drugs may be used for treating conditions other than hypertension, and loop diuretics are not
3 indicated as primary antihypertensives, we will refer to them henceforth collectively as blood-
4 pressure lowering medications.
5

6
7 On the basis of the 5-year interval before the initial prescription, patients were excluded if they had
8 already received any blood-pressure lowering medication (to ensure inclusion of newly treated
9 individuals), or displayed characteristics suggestive of high risk of falls and/or bone fracture, such as
10 hospital admissions for selected causes or prescriptions of selected medications. The former,
11 identified by the ICD-9 code for hospital admissions, included: malignant neoplasm, traumatic injury,
12 Paget's disease, osteomalacia, Cushing syndrome, coeliac disease, hyperthyroidism, hyper-
13 parathyroidism, Parkinson's disease, orthostatic hypotension, blindness, balance disorders, dementia,
14 cerebrovascular disease and chronic liver disease. The selected medications, identified by the ATC-
15 codes of outpatient drug prescriptions, consisted of bisphosphonates, calcitonin, raloxifene,
16 corticosteroids, antineoplastic agents, and medications used for thyroid therapy. With the aim of
17 ensuring enough observation for applying exclusion criteria, patients who did not result registered
18 into the NHS from at least five years before the initial prescription were excluded.
19

20 The patients included into the final cohort accumulated person-years of follow-up from the initial
21 prescription until the earliest date among hospital admission for HF (outcome), death, emigration, or
22 December 31st, 2012.
23

24 **2.3 Cases and controls**

25 Cases were those who experienced the outcome "hospitalization for HF" during the follow-up,
26 identified by the related ICD-9 code (820.x). The earliest date of hospital admission recorded with
27 this code was considered as the event date. Three controls for each case were selected randomly
28 within the cohort after they were matched on gender, age at cohort entry (± 3 years), date of cohort
29 entry, and did not yet have experienced the outcome at the time of the matched case event (index
30 date).
31

2.4 Exposure

For each case and control all blood-pressure lowering medications dispensed from initial prescription until the index date were identified. Prescriptions during the 30-day period before the index date were considered to identify current exposure to any blood-pressure lowering medication. The last prescription before the outcome onset within the current time was considered for classifying patients according to 1) exposure to specific blood-pressure lowering classes, i.e., ACE-inhibitors and ARBs together, α -blockers, β -blockers, CCBs, loop diuretics, and non-loop diuretics; 2) antihypertensive treatment strategy, i.e. if one (monotherapy), or two or more agents (combined therapy) were dispensed. Combined therapy was regarded as either, a fixed-dose combination or an extemporaneous combination of two or more drugs dispensed at the same date.

2.5 Covariates

We included prescriptions of drugs used for selected diseases known to be associated with increased risk of fall (i.e., antidepressants, neuroleptics and hypoglycaemic agents [35,36]). Additionally, we recorded the use of statins, which has been consistently associated with decreased risk of HF [37]. The prescriptions of these medications were recorded for the 5-year period before the initial prescription. Information about the use of other drugs suspected to affect the postural control (i.e., digoxin, benzodiazepines, antiarrhythmics, and antiepileptics [38]) in the 30-day period before the hip fracture was also included. Finally, the diagnosis available from the inpatient charts over five years before the initial prescription date was used to calculate the Charlson comorbidity index [39].

2.6 Data analysis

Two approaches of data analysis were used (Figure 1). One, the case-control approach was used by contrasting the current exposure of each case with that of the three matched controls. A conditional logistic regression for 1:3 matched case-control data was used to estimate the odds ratio (OR), and 95% confidence interval (CI), of HF associated with the current exposure to blood-pressure lowering medications. Estimates were adjusted for the above reported covariates including drug prescriptions during the 5-year period (i.e., antidepressants, neuroleptics, hypoglycaemic agents, and statins) and

1 the 30-day period (i.e., digoxin, benzodiazepines, antiarrhythmics, and antiepileptics) before the
2 index date, as well as the Charlson comorbidity index (categorized according to scores 0, 1 or ≥ 2).
3
4 Two, the case-crossover approach was used to estimate the effect of current exposure on the
5 considered outcome [40]. To this end, the current exposure of each case was contrasted with three
6 previous reference periods (each of 30-day width) within each case patient. A wash-out period
7 between the current and the most recent reference period was allowed to avoid a carryover effect. By
8 comparing cases to themselves at different points in time, the case-crossover approach automatically
9 controls for confounding by attributes that are constant over time. A conditional logistic regression
10 model for 1:3 matched data was again used to estimate the OR for current exposure to **blood-pressure**
11 **lowering medications**. Estimates were adjusted for the use of digoxin, benzodiazepines,
12 antiarrhythmics, and antiepileptics during the current and referent periods.
13
14 It should be considered that, according with the case-crossover design, exposure to **blood-pressure**
15 **lowering medications** and other agents must to be assessed during a time-window large enough to
16 include current and referent periods, as well as the wash-out period. We therefore need a long enough
17 time-window before the index date for assessing exposure of all case patients. For this reason, cases
18 who did not reach at least 6 months of follow-up were excluded. Furthermore, although a shorter
19 time-window was requested for the case-control design, we preferred to use the same exclusion
20 criterion for ensuring results comparability.
21
22 Data were separately analysed for two age subgroups (70-80 and 81-90 years). Shorter (15 days) and
23 longer (45 and 90 days) definitions of exposure were also considered to verify the robustness of case-
24 control and case-crossover findings.
25
26 All analyses were performed using the Statistical Analysis System software version 9.4 (SAS
27 Institute, Cary, NC, USA). Statistical significance was set at the 0.05 level. All p-values were two-
28 sided.

3. RESULTS

3.1 Patients

The selection of the final cohort is detailed in **Figure 2**. The 81,617 patients accumulated 406,953 person-years of observation (on average 5.0 years per patient), and generated 2,331 first hospital admissions for HF. Of these, the 178 patients who experienced the outcome within the first six months of follow-up were excluded. The remaining 2,153 HF hospitalizations were included as cases and were matched to 6,450 controls. At the date of the initial prescription mean age (\pm SD) of cases and controls was 79 years (\pm 5 years), and 24% of them were men.

Some selected characteristics of the study population, as well as of risk and referent periods within cases, are summarized in **Table 1**. HF was preceded by a 30-day blood-pressure lowering medication treatment in about one third of the cases with no significant difference from controls. There was no evidence that cases and controls differ for the currently employed treatment strategy. A higher proportion of cases than controls was currently exposed to α -blockers ($p=0.036$), loop diuretics ($p<0.001$), benzodiazepines ($p<0.001$), and antiepileptic agents ($p<0.001$). The proportion of patients under statin treatment was lower in cases than in controls ($p=0.008$), whereas the reverse was observed for antidepressants and neuroleptics (both $p<0.001$). Charlson comorbidity index was similar in cases and controls. Cases were more frequently exposed to loop diuretics ($p=0.021$) during the current period than during the referent one.

3.2 Case-control estimates

There was statistical evidence that current exposure to α -blockers and loop diuretics increased the HF risk of 69% (95% CI 4% to 176%) and 67% (95% CI 28% to 118%) respectively (**Figure 3**). Current exposure to loop diuretics resulted significantly associated with the HF risk among both younger and older patients, whereas evidence that α -blockers exert their action on the considered outcome resulted only for older patients. (**Table 2**). There was no evidence that current exposure to blood-pressure lowering medications as a whole (including or excluding loop diuretics), as well as blood-pressure lowering medication dispensed as monotherapy or combined therapy affected the HF risk (**Figure 4**).

3.3 Case-crossover estimates

Figure 3 shows that current exposure to loop diuretics significantly increased the HF risk of 49% (95% CI 5% to 110%). The risk associated with current use of α -blockers observed from case-control estimates was not confirmed from the case-crossover estimate. However, older patients currently using α -blockers and loop diuretics had increased HF risks of 88% (95% CI 1% to 248%) and 82% (95% CI 10% to 200%) respectively (**Table 2**). Again, there was no evidence that current exposure to **blood-pressure lowering medications** as a whole (including or excluding loop diuretics), **as well as treatment strategy affected the HF risk (Figure 4)**.

Sensitivity analysis

Results did not substantially change by shortening at 15 days or lengthening at 45 and 90 days the definition of current exposure (results shown in **Supplementary Table 2**).

4. DISCUSSION

This study shows that elderly subjects newly treated with **blood-pressure lowering medications** as a whole in a real life setting did not exhibit a greater risk of HF. Nevertheless, considering the single classes, current use of loop diuretics resulted consistently associated with an increased HF risk among the entire cohort of patients aged 70 to 90 years (1.5-fold increased risk), as well as among those aged 81-90 years (1.8-fold increased risk). The category of older patients currently exposed to α -blockers had also a 1.9-fold increased HF risk.

The mechanism for loop diuretics involves rapid reduction in circulating plasma volume and for α -blockers vasodilatation due to α -adrenergic blockade [41]. Because advanced age is associated with diminished organ and homeostatic reserve, the susceptibility of older people to the adverse effects of these mechanisms is correspondingly greater.

Several features of this study should be mentioned to interpret these findings. First of all, the increased risk was observed using two different approaches, namely case-control and case-crossover designs.

1 Case-control is vulnerable to confounding, including confounding due to physical and cognitive
1
2 2 conditions typical of advanced age which often remain unmeasured. The case-crossover design is not
3
4 3 vulnerable to confounding by factors that remain constant within individuals, but is vulnerable to
5
6 4 confounding arising from time-trends in exposure or confounders. Although these designs use entirely
7
8 5 different sets of controls, very similar results were obtained in the current application. This doubtless
9
10 6 strengthens the validity of our findings.
11
12

13
14 7 Because we designed the study to investigate the acute effect of taking **blood-pressure lowering**
15
16 8 **medications** in the period before the HF outcome, the findings do not indicate a longer term lowering
17
18 9 effect of loop diuretics or antihypertensive agents on bone mineral density [18,23]. Rather, they likely
19
20 10 reflect the hypotensive effect of impairing sympathetic vascular influences or reducing blood volume
21
22 11 [42,43] with associated symptoms such as dizziness, fainting, or syncope [44,45]. Indeed, impaired
23
24 12 blood pressure homeostasis [46] and urinary symptoms during night-time [17] could facilitate
25
26 13 injurious falls.
27
28
29

30
31 14 We also remark that a case-crossover design needs of a sufficient time frame for retrospectively
32
33 15 investigating the exposure of interest. Evidence suggests that initiation of **blood-pressure lowering**
34
35 16 **medication** in the immediate post-exposure period is largely associated with orthostatic hypotension
36
37 17 [42,45,47]. This likely explain why, in contrast with other studies involving elderly patients [16], we
38
39 18 did not find that antihypertensive drug treatment as a whole increased the risk of HF. **Rather, the case-**
40
41 19 **crossover design sheds light on the differential effect of switching between drug classes.** Similar
42
43 20 findings were reported by a recent case-crossover study, which showed a two-fold increased risk of
44
45 21 HF shortly after starting loop diuretic treatment [17]. On the other hand, we did not confirm results
46
47 22 from case-only studies reporting significant associations between transitory use of β -blockers [14],
48
49 23 ACE inhibitors [16], ARBs [25] and CCBs [48] with the risk of falls. At our best knowledge, there
50
51 24 are no other studies that demonstrated an increased risk of HF with use of α -blockers.
52
53
54
55
56
57
58
59
60
61
62
63
64
65

1 Furthermore, we enlightened that the risk of HF is significantly increased among users of
2 benzodiazepines, antiepileptics, antidepressants and neuroleptics, confirming the increased risk of
3 falls during treatment with psychotropic drugs [38].

4
5 Finally, the size of the observed association, jointly with the prevalence of loop diuretic prescriptions
6 in our patient sample (slightly less than 3%), suggests that less than 3% of HFs in elderly
7 hypertensives are attributable to acute use of loop diuretics. Etiological fraction is expected to be
8 about 5% for α -blockers. This means that, in our setting, almost one out of twelve hospital admissions
9 for HF are probably due to current exposure to antihypertensive drugs. This represents a warning that
10 should always remind physicians of the possibility of accidental falls and their related consequences
11 when antihypertensive treatment is prescribed in the elderly.

12 This study has some limitations. One, we were unable to determine whether participants adhered with
13 drug prescriptions. However, reliable measures of adherence can hardly be employed in large-scale
14 population studies. Furthermore, poor adherence would have made the adverse effects even greater
15 with respect to α -blockers and loop diuretics. Two, it is impossible to determine whether the observed
16 HFs were related to falls. However, a study on post-menopausal women showed that more than 95%
17 of HFs are linked to a fall [9], which suggests that this was indeed the main risk factor for the
18 considered outcome. Three, because our HCU databases did not report diagnostic information,
19 patients may have had conditions other than hypertension. This clearly applies in the case of loop
20 diuretic use, for which the commonest indication is congestive heart failure. However, if we consider
21 the clinical indications of the use of antihypertensive drugs in Italy, hypertension per se represents by
22 far the most common diagnosis (73%), and only about 20% are prescribed for angina pectoris,
23 myocardial infarction and heart failure, and less than 1% for non-chronic indications, such as oedemas
24 [49]. Four, case-crossover estimates are open to bias from confounders that vary with time including,
25 in the present study, seasonality of HF risk [50]. However, although a certain seasonality in the risk
26 of fractures has been reported [51], to the best of our knowledge there is no evidence that this aspect
27 might substantially affect antihypertensive therapy. Rather, we cannot exclude that worsening clinical

1 profile (likely leading to change therapeutic strategy and increase the risk of fall) may partly explain
2 the observed risk excesses.

5. CONCLUSION

3
4
5
6
7
8
9
10
11
12 This large population-based study in a setting of real practice confirms previous evidence of an
13
14 increased risk of HF among elderly who newly use loop diuretics. Some evidence that α -blockers
15
16 might play a causal role in the onset of HF has been also supplied. Given the potential for bias and
17
18 the conflicting results from the existing literature on this issue, additional high quality studies are
19
20 needed. Meanwhile, with the aim of reducing the burden of HF, which ranges from the individual
21
22 disability to the social costs, it is important to direct every effort to counteract the worldwide
23
24 increasing trend. In this scenario, the careful consideration of the most appropriate antihypertensive
25
26 drug strategy plays a fundamental role.

SOURCES OF FUNDINGS

Supports for this study come from the Italian Minister of the Education, University and Research grants (“Fondo d’Ateneo per la Ricerca” portion, year 2014).

DISCLOSURES

G.C. received research support from the European Community (EC), the Italian Agency of Drug (AIFA), and the Italian Minister for University and Research (MIUR). He took part to a variety of projects that were funded by pharmaceutical companies (i.e., Novartis and GSK). He also received honoraria as member of Advisory Board from Roche.

G.M. has received honoraria for participation as speaker/chairman in national/international meetings from Bayer, Boehringer Ingelheim, CVRx, Daiichi Sankyo, Ferrer, Medtronic, Menarini Int., Merck, Novartis, Recordati and Servier.

P.M., M.M.C., F.R., L.M., G.A. declare that they have no conflict of interest.

COMPLIANCE WITH ETHICAL STANDARDS

Research involving human participants and/or animals: The present research did not involve any trial on human participants or animals.

≥2	48 (2.2%)	122 (1.9%)	-		

ACEs: Angiotensin-converting enzyme inhibitor; ARBs: Angiotensin receptor blockers; CCBs: calcium channel blockers.

a According to chi-square test or its version for the trend (categories of the Charlson comorbidity index score).

b Within 30 days before the index date.

c Within five years before the index date.

Table 2. Case-control and case-crossover estimate of the relationship between current use of **blood-pressure lowering medications** and the risk of hip fracture in younger (70 to 80 years old) and older (81-90 years old) patients

		Younger patients OR (95% CI)	Older patients OR (95% CI)
ACEs or ARBs	Case-control	0.69 (0.58 to 0.82)	0.82 (0.67 to 1.01)
	Case crossover	0.91 (0.73 to 1.13)	0.89 (0.69 to 1.15)
CCBs	Case-control	1.08 (0.82 to 1.43)	0.84 (0.60 to 1.18)
	Case crossover	0.95 (0.66 to 1.36)	1.44 (0.89 to 2.35)
β -blockers	Case-control	0.99 (0.75 to 1.32)	1.21 (0.85 to 1.72)
	Case crossover	0.78 (0.56 to 1.10)	1.03 (0.67 to 1.58)
α -blockers	Case-control	1.39 (0.57 to 3.39)	1.86 (1.03 to 3.35)
	Case crossover	1.40 (0.47 to 4.15)	1.88 (1.01 to 3.48)
Loop diuretics	Case-control	1.88 (1.28 to 2.74)	1.52 (1.04 to 2.21)
	Case crossover	1.36 (0.84 to 2.19)	1.82 (1.10 to 3.00)
Non-loop diuretics	Case-control	0.79 (0.63 to 1.00)	0.89 (0.68 to 1.17)
	Case crossover	0.94 (0.69 to 1.29)	1.31 (0.92 to 1.88)
Any agent	Case-control	0.93 (0.80 to 1.08)	0.95 (0.80 to 1.12)
	Case crossover	1.03 (0.86 to 1.23)	1.16 (0.94 to 1.43)
Monotherapy	Case-control	1.10 (0.92 to 1.30)	0.96 (0.79 to 1.17)
	Case crossover	1.10 (0.90 to 1.34)	1.13 (0.88 to 1.44)
Combined therapy	Case-control	0.71 (0.57 to 0.88)	0.92 (0.72 to 1.18)
	Case crossover	0.90 (0.68 to 1.17)	1.21 (0.89 to 1.65)
Any agent with the exception of loop diuretics	Case-control	0.87 (0.75 to 1.01)	0.91 (0.77 to 1.08)
	Case crossover	1.00 (0.83 to 1.19)	1.13 (0.91 to 1.40)
Monotherapy	Case-control	1.01 (0.85 to 1.20)	0.95 (0.78 to 1.16)
	Case crossover	1.07 (0.87 to 1.31)	1.16 (0.90 to 1.49)
Combined therapy	Case-control	0.78 (0.62 to 0.97)	0.84 (0.65 to 1.09)
	Case crossover	0.86 (0.65 to 1.14)	1.08 (0.78 to 1.49)

ACEs: Angiotensin-converting enzyme inhibitor; ARBs: Angiotensin receptor blockers; CCBs: calcium channel blockers

1 **Table S1**

Blood pressure lowering class	Active ingredient
<i>Single agent</i>	
ACEs or ARBs	Captopril, enalapril, lisinopril. Perindopril, ramipril, quinapril, benazepril, cilazapril, fosinopril, trandolapril, spirapril, delapril, moexipril, zofenopril, losartan, eprosartan, valsartan, irbesartan, candesartan, telmisartan, olmesartan medoxomil.
CCBs	Amlodipine, felodipine, isradipine, nifedipine, nimodipine, nisoldipine, nitrendipine, lacidipine, manidipine, barnidipine, lercanidipine, verapamil, gallopamil, diltiazem.
β -blockers	Pindolol, propranolol, timolol, sotalol, nadolol, metoprolol, atenolol, acebutolol, betaxolol, bisoprolol, celiprolol, nebivolol, labetalol, carvedilol.
α -blockers	Methyldopa (levorotatory), clonidine, moxonidine, doxazosin.
Loop diuretics	Furosemide, piretanide, torasemide.
Non-Loop diuretics	Hydrochlorothiazide, chlortalidone, metolazone, indapamide, spironolactone, potassium canrenoate, canrenone, hydrochlorothiazide and potassium-sparing agents, butizide and potassium-sparing agents, furosemide and potassium-sparing agents.
<i>Fixed combination</i>	
ACEs + CCBs	Enalapril and lercanidipine, perindopril and amlodipine, ramipril and felodipine, delapril and manidipine.
β -blockers + diuretics	Bisoprolol and thiazides, nebivolol and thiazides, metoprolol and thiazides combinations, oxprenolol and other diuretics, atenolol and other diuretics combinations, atenolol and other diuretics.
ACEs + diuretics	Captopril and diuretics, enalapril and diuretics, lisinopril and diuretics, perindopril and diuretics, ramipril and diuretics, quinapril and diuretics, benazepril and diuretics, cilazapril and diuretics, fosinopril and diuretics, delapril and diuretics, moexipril and diuretics, zofenopril and diuretics.
ARBs + CCBs	Olmesartan medoxomil and amlodipine.
ARBs + diuretics	Losartan and diuretics, eprosartan and diuretics, valsartan and diuretics, irbesartan and diuretics, candesartan and diuretics, olmesartan medoxomil and diuretics, azilsartan medoxomil and diuretics.

1 **Table S2.**

		OR (95% CI)		
		15 days	45 days	90 days

	Case crossover	0.91 (0.69 to 1.19)	1.14 (0.90 to 1.43)	0.87 (0.70 to 1.08)

AUTHOR DECLARATION FORM

At submission, **EVERY AUTHOR** listed in the manuscript must **READ** and **COMPLETE** the following statements on:

- (A) Authorship Responsibility, (B) Authorship Criteria, (C) Authorship Contribution, (D) Funding Disclosures, (E) Contributor Disclosures/Acknowledgments, and (F) Conflicts of Interest Disclosures.

It is important that you return this form as early as possible in the publication process. **EVERY AUTHOR MUST COMPLETE AN INDIVIDUAL COPY OF THE FORM, AND EVERY SECTION OF THE FORM MUST BE COMPLETED.** We will **NOT** consider your manuscript for publication until every author has completed the form and returned it to us.

Your name (please print): PAOLO MAZZOLA _____ E-mail: paolo.mazzola@unimib.it _____

Journal name: DRUGS & AGING _____ Corresponding author: GIOVANNI CORRAO _____

Manuscript title: Antihypertensive medications and risk of hip fracture in the elderly _____

A. AUTHORSHIP RESPONSIBILITY

I certify that **ALL** of the following statements are correct (**PLEASE CHECK THE BOX**).

- The manuscript represents valid work; neither this manuscript nor one with substantially similar content under my authorship has been published or is being considered for publication elsewhere (except as described in the manuscript submission); and copies of any closely related manuscripts are enclosed in the manuscript submission; **AND**
- For manuscripts with more than one author, I agree to allow the corresponding author to serve as the primary correspondent with the editorial office and to review and sign off on the final proofs prior to publication; or, if I am the only author, I will be the corresponding author and agree to serve in the roles described above.
- For manuscripts that are a report of a study, I confirm that this work is an accurate representation of the trial results.

B. AUTHORSHIP CRITERIA

To fulfil all of the criteria for authorship, every author of the manuscript must have made substantial contributions to **ALL** of the following aspects of the work:

- Conception and planning of the work that led to the manuscript or acquisition, analysis and interpretation of the data, or both; **AND**
- Drafting and/or critical revision of the manuscript for important intellectual content; **AND**
- Approval of the final submitted version of the manuscript.

I certify that I fulfill **ALL** of the above criteria for authorship (**PLEASE CHECK THE BOX**).

C. AUTHORSHIP CONTRIBUTION

I certify that I have participated sufficiently in the work to take public responsibility for (**PLEASE CHECK 1 OF THE 2 BOXES BELOW**):

- Part of the content of the manuscript; **OR**
 The entire content of the manuscript.

D. FUNDING DISCLOSURES

PLEASE CHECK 1 OF THE 2 BOXES BELOW:

- I certify that no funding has been received for the conduct of this study and/or preparation of this manuscript; **OR**
 I certify that all financial and material support for the conduct of this study and/or preparation of this manuscript is clearly described in the Compliance with Ethical Standards section of the manuscript.

Some funding organizations require that authors of manuscripts reporting research deposit those manuscripts with an approved public repository.

Please check here if you have received such funding.

E. CONTRIBUTOR DISCLOSURES

All persons who have made substantial contributions to the work reported in the manuscript (e.g. data collection, data analysis, or writing or editing assistance) but who do not fulfill the authorship criteria **MUST** be named with their specific contributions in the Acknowledgments section of the manuscript. Groups of persons who have contributed may be listed under a heading such as 'Clinical investigators' and their function described. Because readers may infer their endorsement of the manuscript, all persons named in the Acknowledgments section **MUST** give the authors their written permission to be named in the manuscript.

I certify that all persons who have made substantial contributions to this manuscript but who do not fulfill the authorship criteria are listed with their specific contributions in the Acknowledgments section in the manuscript, and that all persons named in the Acknowledgments section have given me written permission to be named in the manuscript.
